1.1 The FINken Robot Platform

The FINken project aims to create a swarm of autonomously flying quadcopters to research swarm intelligence behaviour on robots. Many algorithms in swarm intelligence are based on distance-values. On this occasion it is im-portant to find a sensor that is capable to measure distances and to integrate it into the FINken robots.

source

1.1.1 Environment

Creating a swarm of flying robots is a rather difficult task. Therefore the environment for the FINken robots is created to protect the robots from mechanical damage and to function well with the sensors the robot uses.

The FINken robots fly in an enclosed area of 2m by 3m that can be expanded to about 4m by 3m. The flight area is enclosed by netting and ultrasound-reflecting foil. Usually the altitude of operation is between 50cm to 1m. To prevent damage when the quadcopters crash the floor is covered with mats that work well with ultrasound and infrared sensors. It is possible to create virtual environmental factors by using a projector and an rgb-sensor mounted on top of the robots. This virtual environment can be used assign a certain task to the robot, e.g. finding the brightest spot.

foto

1.1.2 Actuators and Dynamic

put this
subchapter
into intro-
duction

The FINken Robot is a quadcopter. Like most quadcopters the FINken Robots are propelled by four rotors that are directly attached to a brushless motor. In combination the motors can be controlled to change the direction of the thrustvector (pitch and roll), to change the overall amount of lift generated (thrust) and to change the orientation of the airframe (yaw). The speed of each motor is controlled by an the LisaMX 2.1 autopilot-board[1] using the opensource autopilot firmware Paparazzi[2].

The robots are highly dynamic-the robots have enough acceleration to leave the operating environment in any possible direction. This is mainly because the robots need lots of payload capacity to carry different sensors and computing power, with enough headroom to make changes in the future.

1.1.3 Sensor Concept

The sensors used by the FINken robots are usually used for two purposes: To enable the robots to fly autonomously and to interact with other robots and the environment.

Autonomous Flying

To form a swarm the robots need to function as single individuals first-that means not crashing into walls, ceiling, floor or other robots. Of course the sensors needed for autonomous flight must not be disturbed by anything else.

height con-
trol

wall avoid

Interaction

The FINken robots shall be able to do more than simply not crashing. Of course sensor values needed for autonomous flight can also be used to interact

with the robots environment, but there are also sensors that are exclusively used for interaction.

To interact with an environment a solution is necessary that works well in the laboratory. The environment of the robots shall be changed without changing the physical layout of the lab. An environmental factor that can be easily changed is the lighting of the flying area. In the swarmlab a projector can be used to affect the quadcopters. To measure the current lighting situation an rgb color sensor is mounted on top of the copter.

The range-sensor is also mainly used for interaction. Ranging values enable the FINken robots to implement attraction-repulsion-behaviour.

1.1.4 Hardware interfering with ranging

There are different ranging technologies that might be used in a FINken quadcopter. However there are different components that can interfere with the new sensor that shall be integrated e.g. by disturbing the measurements made by the new sensor.

Sonar Sensors Sonar sensors to measure distances of the nearest object in four directions (front, back, left, right)

Motors Four brushless motors that may cause RF-interference and noise

Telemetry BTLE-/Zigbee modules to exchange data with the ground station

RC-Control 2.4GHz based Radio Control to manually control the robots

Power-Supply Lithium polymer batteries with nominally 6.6V output voltage that is **fink3?**
converted to 5V and 3.3V by the power distribution hardware

Payload The overall weight of the copter in the current configuration is about g **weight**
with about g headroom for additional equipment **payload**

Size The copter has a rotor to rotor distance of 10cm, and a sensor tower that is about 4cm by 4cm wide to use the existing mounting holes would be favourable

1.2 Evaluation of Existing Ranging Solutions

mehr fokus
auf andere
copter pro-
jekte

There are some technologies that can be used for ranging, however the usual application for most of those technologies in research is positioning. For that reason it is interesting to search for positioning applications that use range measurements, however many of those positioning technologies are based on other principles than multilateration¹. [3]

The usual technologies used for ranging are based on time of flight measurements, signal strength, optical tracking, and phase difference measurements in signals.

1.2.1 Indoor Time of Flight

The obvious approach for replacing the GPS signal that is available outdoors is to use a similar approach indoors. <http://robotics.eecs.berkeley.edu/pister/290Q/Papers/Location/Lanzisera%20RF%20TOF%20WISES06.pdf>

quellify

states, that an accuracy of $2.6m_{RMS}$ was achieved indoors. With an operating area only $2m$ wide this approach is not suited for our robots. However this research is focused on using cheap sensor-nodes.

quellify

Another approach to provide an indoor GPS-like solution is iGPS. [http://www.nikonmetrology.com/de_EU/Produkte/Grossvolumige-](http://www.nikonmetrology.com/de_EU/Produkte/Grossvolumige-Messaufgaben/iGPS/iGPS)

quellify

[Messaufgaben/iGPS/iGPS](http://www.nikonmetrology.com/de_EU/Produkte/Grossvolumige-Messaufgaben/iGPS/iGPS) however is not ranging-based but uses angulation as underlying technology and is therefore useless to us. * iGPS http://porto.polito.it/2438175/2/IJAMT_iGPS_and_LT.pdf

¹The usual methods for positioning are: *multilateral*—which is what we are interested in because only ranging measurements are used, *multiangular*—which is no use to us, because angle measurements are used and by *orientating in a map* with different factors like beacon-positions—which is also no use to us.

deka-wave

1.2.2 Cricket / Active Bat

A very clever approach to ranging is used by ranging solutions like cricket and active bat. RF-Signals travel at the speed of light and therefore you need to be able to measure very short timings in time of flight scenarios. Sound however travels at a speed much slower than RF. Cricket and Active Bat use this to measure the time difference an RF-signal and an ultrasound pulse need to travel from transmitter to receiver to calculate the range between two sensor nodes.

Quelle,
Quelle

There are two big problems with this approach that stem from the current setup of the FINKen-Robots. The FINKen Robots use ultrasound sensors to measure the distances to nearby objects. Those technologies would interfere with the ultrasound sensors already used and a replacement would be needed.

thunderstorm
and lightning
very very
frightning

Another problem is the noise created by motors and propellers. The sound made by the quadcopters is not ending in the hearable spectrum but also extends to the ultrasound range.

1.2.3 RSSI-based ranging

A property that can be used to do RF-based ranging is signal strength. The further the source of the signal is away the weaker the signal gets. RSSI-based ranging is done for several different technologies: Bluetooth, WLAN, RFID. There are even approaches using maps created of different RSSI-ranging sources. http://www.gnss.com.au/JoGPS/v9n2/JoGPS_v9n2p122-130.pdf

measure
noise,
PWM-
frequency
of speedcon-
trollers

The main factor that rules out RSSI-based ranging is that radio-waves are not propagated equally in every direction. Antenna-orientation might have a much bigger impact on signal strength than distance. Additionally radio waves

1.2.4 External Tracking

Most projects use external tracking to measure the position and orientation of the quadcopters.

refs

research
performance
statistics
for ranging
solutions

With external tracking high accuracy for ranging and orientation can be achieved with a high update frequency.

A huge drawback to this method is that many components are used that need to be integrated into the environment and cannot be carried by the robots themselves. For swarm robotics this is not an ideal solution as using external tracking would mean communicating with some kind of centralized tracking interface-destroying the scalability and the priciple of local interaction leading

price

to global beheaviour.

1.2.5 Atmel RTB, Dresden Elektronik, Meterionic

2 Concept

2.1 Hardware

2.1.1 Ranging Hardware

There are several different possible hardware platforms for the Atmel ranging software. At the time this thesis started however we only had a precompiled library for the Atmel ranging modules . For the evaluation scenario those modules are quite useable, but there are better options available with the binaries for other hardware platforms. On the copters we want to use \$Module from dresden elektronik which is already integrated into the new hardware revision of the FINken robots.

exact name

The disadvantage of the Atmel sensors is that they are not designed for production use but as development platforms and therefore are quite big and heavy and not really suited to be used on the FINken quadcopters. It is possible however to build a simmlar hardware setup that is much smaller by using smaller packages of the same chips, leaving lots of unused PCB area and unused connectors.

2.1.2 Autopilot

The FINken robots use the LISA/MX autopilot board in hardware revision 2.1. This board is used for higher level auto pilot functions as well as pure stabilization—unlike other UAV projects where there are different units for

stabilization control and higher level functions like pathfinding. This means that all sensors are connected to this board; every computation from evaluation of sensor input to the output of PWM signals to the motors controllers is done on this board.

2.2 Interconnect

There are different solutions to connecting the ranging board to the Paparazzi autopilot. All of the following methods of connecting hardware are supported by the LISA/MX board and one has to be chosen for the new ranging sensors.

2.2.1 Pulse width modulation / Analog value

Using a single GPIO pin or analog value is completely impractical, but a good example to explain the problems the honest solutions need to address.

First of all there is a limited number of GPIO or ADC-pins on both boards. On the autopilot board those pins are quite rare, especially because they cannot be shared easily between components. The second problem is that we do not only need to read a range value from the sensor but we also need to tell the sensor which value to fetch. Therefore some kind of bidirectional communication between autopilot and sensor need to take place. The big advantage of using a GPIO pin would be that only one single wire¹ would be needed to connect autopilot and sensor.

2.2.2 UART

The "Universal Asynchronous Receiver/Transmitter"-Protocol uses two wires to establish communication between devices. [14]

¹Plus two wires for voltage supply

The Disadvantage of UART-style Protocols is that it is a bidirectional connection. That two pins are needed on sender and receiver side and if another device should be connected two new pins are needed. On the Lisa/MX autopilot there are 4 dedicated UART connections that might be used, but already 3 of them are used.

2.2.3 SPI

2.2.4 CAN bus

2.2.5 I2C

I2C is a two-wired bus protocol that can be used to connect multiple slave devices to one master device. There already are multiple sensors connected to the autopilot via I2C. All of the ultrasound-sensors and also the optional color sensor use I2C to communicate with the autopilot. The autopilot board also supports to have two independent I2C-networks.

Especially the fact that there already is a sensor network on the Finken makes it the best choice as a communication protocol for the new sensor.

problem:
slaves can
block the
bus

3 Implementation

Somehow the sensor data needs to find its way into the control loops of the autopilot. We have established that i2c is the hardware solution to transmit the data.

Now it is important to pin down in which way the measurements get triggered and when and how the result is transmitted back.

3.1 Communication Protocol

There are two possible ways to talk to the sensor. You can define independent commands to start a measurement and retrieve data. The obvious disadvantage of this method is, that there is a bit of communication overhead and the master device won't read the data from the sensor as soon as it is possible—the master might even start a new measurement without even reading the result at all.

The other way to do things is that the slave device writes the data onto the bus as soon as it is arriving. This way of sending results however has disadvantages that are far worse than reading measurements a bit later and even missing some measurements. Those disadvantages are caused by the way i2c handles slave writes.

The sensor has different functions described by i2c-registers that can be written to by the master device. The registers and the format of the range response are described by *i2c_interface.h*.

"TWI",
"Phillips-
I2C", "..."

3.2 Paparazzi Module for Ranging

Treiber für
Ranging

(optional) Treiber
für Pseudo
GPS

Addressing is done using the unique aircraft id of the individual robots. Because the short addresses for the ranging nodes are 16 bit long and the aircraft ids are 8 bit values it is feasible to use a fixed prefix together with the ac-id as node addresses.

3.3 Python Scripts

For testing the sensor nodes and also for acquiring the data for evaluating the sensors I set up a RaspberryPi minicomputer as i2c master. Using this setup for testing has proven really effective even before integrating attaching the sensor nodes to one of the finken robots. Python might also be a very powerful tool to prototype mathematical processing of the sensor inputs like filtering and fusion of different ranging results.

i2cranging.py contains functions for the master side of I2C communication. Those can either be used from the python PEPL or by other scripts. *poll_range.py* contains a convenient method to take continuous range readings from the unix shell and is mainly used to generate csv-files with ranging values.

4 Evaluation

4.1 Robustness of Implementation

For use in the FINken robots not only the quality of the measurements is relevant.

4.1.1 Bus hangup

I2C is an easy to implement and use bus protocol. One of the drawbacks of I2C is that misbehaving clients are able to block the whole bus.

At the moment the ranging sensors cause bus hangups, when rangings are requested to often. _____

measure

4.1.2 i2c errors per time

Another problem that may occur is that i2c data packets can get lost. _____

measure

4.1.3 Integration Test for Quadcopter

4.2 Ranging Accuracy

4.2.1 Frequency Selection

The frequencies used by the ranging can be chosen. Especially because normal 2.4GHz wifi and several other technologies are using the same frequencies as the ranging modules the selection of a well working one is crucial to ranging performance.

measured difference between meeting, empty lab and open field

4.2.2 Influence of DQF on Range Values

One value the ranging api provides is the DQF¹-value. It is reasonable to expect a huge amount of scatter for lower DQF values. As Figure 4.1 shows this is not how the range value behaves.

For the values measured with 1m real distance we can see that the values measured with lower quality do not have the same mean value as those with higher quality. Also values measured with lower quality are closer to each other than those with higher signal quality. As long as we only look at the values taken at 1m real distance it seems like we could be able to improve the range estimate by including the dqf value into the computation of the distance. To do that this behaviour would need to be stable across different distances, i.e. no matter if the measurement is taken at 1m or 3m distance the when the dqf is low the measured range is lower and if dqf is high the measured range is higher.

¹Data Quality Factor

4.2.7 Ranging on FINken Robots

4.3 Properties of a Distance Function

The ranging sensor on the FINken robot shall be used to provide a distance between two quadcopters, similar to a distance measure used in swarm intelligence algorithms. In the pure mathematical sense a distance function has to fulfill certain properties.

If $f(x, y)$ is a distance function it has to have the following properties.

$$f(x, y) \geq 0 \tag{4.1}$$

$$f(x, y) = 0 \iff x = y \tag{4.2}$$

$$f(x, y) = f(y, x) \tag{4.3}$$

$$f(x, z) \leq f(x, y) + f(y, z) \tag{4.4}$$

Of course the value measured by any real sensor will not completely accomplish to satisfy those conditions. For use in swarm robotics it is therefore very interesting to know in which way the range values break the pattern of a mathematical distance function.

4.3.1 Non-negativity and Coincidence

The first property of a mathematical distance measure to look at is non-negativity. This is quite easy: The values yielded by the ranging modules are clearly positive. Also the property of coincidence is always given. Each module has a unique address and is therefore able to check, if it is ranging itself. Having two modules occupy the same physical spot is obviously not possible so there cannot be two different modules that are equivalent in a mathematical sense.

4.3.2 Symmetry

In this section the following notation will be used: $A \rightarrow B$ means a range reading is taken from node A with B as reflector node.

Symmetry is a property that can not be achieved by the ranging sensors because of noise. A range reading $A \rightarrow B$ will not be equal to the reading for $B \rightarrow A$ just because the two readings will be altered by noise. The question that remains is: Do we have the same error for both directions.

measure,
plot, evaluate

4.3.3 Triangle Inequality

The Triangle Inequality will also be broken by noise. I.e. if we measure $d(A, B) + X + d(B, C) + X$ and $d(A, C) + X$ the measurement error X might as well break the condition of the Triangle Inequality.

4.4 Conclusion

5 Future Work

5.1 Formation Flying using Swarm Behaviour

One of the next steps is to algorithms from swarm intelligence to the FINken robots. The robots should be able to form a stable formation by using virtual attraction and repulsion forces to hold a given distance to their neighbors. If those distances are stable enough formations like triangle meshes can be formed.

get simulation data

übertragen

5.1.1 Direction

A value that the ranging sensors don't yield is the direction of the other sensor it is ranging with. For use in swarm algorithms this is a problem: Normally we compute a force towards or from the other swarm entities that is based on distance and direction. This way is still blocked for us as we can't measure direction.

5.2 Flying with Pseudo-GPS

One of the things that can be done with ranging is position estimation via multilateration. Even if the FINken project is mainly interested in gaining a viable distance measure between individuals in a swarm a position estimate

would be beneficial for the performance of the autopilot-especially as the normal usecase for the Paparazzi autopilot is outdoors and with a GPS reciever attatched.

To integrate positional data into the FINken two steps are needed: Implementing the multilateration algorithm on the sensors and writing a new GPS module that uses the data from the sensor. An additional benefit of using anchor nodes to compute a position estimate is that we can find out our current heading and the direction of other swarm entities much easier
